Breadth-First Search

uninformed search

search strategy that uses no problem-specific knowledge

informed search

search strategy that uses problem-specific knowledge to find solutions more efficiently

greedy best-first search

search algorithm that expands the node that is closest to the goal, as estimated by a heuristic function $h(n)$

Heuristic function?

Heuristic function?

Heuristic function? Manhattan distance.

A* search

search algorithm that expands node with lowest value of $g(n) + h(n)$

$g(n)$ = cost to reach node

$h(n)$ = estimated cost to goal

A* Search

Heuristic Function $h(n)$

The heuristic function $h(n)$ tells A^* an estimate of the minimum cost from any vertex n to the goal. It's important to choose a good heuristic function.

Manhattan method

This method of computing $h(n)$ is called the **Manhattan** method because it is computed by calculating the total number of squares moved horizontally and vertically to reach the target square from the current square. We ignore diagonal movement and any obstacles that might be in the way.

$$h = |x_2 - x_1| + |y_2 - y_1|$$

The Euclidean Distance Heuristic:

Sometimes we might prefer a path that tends to follow a straight line directly to our destination. This heuristic is slightly more accurate than its Manhattan counterpart. If we try run both simultaneously on the same maze, the **Euclidean** path finder favors a path along a straight line. This is more accurate but it is also slower because it has to explore a larger area to find the path.

$$h = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

Make an **open list** containing only the **starting node**

Make an **empty closed list**

While (the **destination node** has not been reached **and** **open list** is not empty):

Consider the node with the lowest f score in the **open list** (call it **current_node**)

If (this node is the **destination node**):

 We are finished (**reconstruct** the path from start to destination)

Else:

Put **current_node** in the **closed list**

Look at all of its **neighbors**:

For each neighbor of **current_node**:

If (**neighbor** is not within the **grid bounds** **or** is an **obstacle**):

Skip this **neighbor**

If (**neighbor** is in the **closed list**):

Skip this **neighbor**

Calculate the cost (g) to reach the **neighbor** from **current_node**:

Set **h** as the heuristic estimate from the **neighbor** to the **goal**

Calculate $f = g + h$

If (**neighbor** is in the **open list** and the new **g** value is lower than the old **g** value):

Update the **neighbor** with the new, lower **g** value

Change the **neighbor's** parent to **current_node**

Else if (**neighbor** is not in both lists):

Add the **neighbor** to the **open list** and set its **g**, **h**, and **f** values

Set **current_node** as the parent of the **neighbor**

If **open list** is empty:

No path is found, return **None**
